

Lecture 3 & Lab 3

update to tables

1. Insert statements

```
1  -- should specify all values
2  insert into {tab1} values ({val1}, {val2}, {val3})
3
4  -- furthermore, values match columns one by one
5  -- other column will be inserted NULL automatically
6  -- It may occur error for mandatory columns
7  insert into {tab1}({col1}, {col2}) values({val1}, {val2})
8
9  -- if we want to insert a string with a single quote
10 insert into student(name) values('Bob't'); -- Bob't here
```

2. delete statements

```
1  -- remove all the tuples in the tab1
2  delete from {tab1}
```

Query -- select

1. format

```
1  select {col1}, {col2}, {col3}... from {tab1}, {tab2}, {tab3}
2  where {conditions}
```

column name don't need ''

2. query for all columns

```
1  select * from {tab1}
```

Remark: This query is frequently used when you don't remember column names. But it would flood the database if the data is large. (In the application programs)

select with restrictions

1. Reason:

when you are interested in only a small subset or only want to return some of the rows.

2. Filtering(rows)

1. overview

1. perform in the `where` clause

2. conditions are usually expressed by a column name

3. only rows for which the condition is true will be returned

4. if you want to filter the columns, just filter it behind the "select"

2. example

```
1 | select * from movies where country = 'us'
```

3. what you compare

```
1 | a number
2 | a string constant: must be quoted between single-quotes
3 | another column(same table or another)
4 | result of a function
```

3. select without From or Where

1. property

never alter any table

might be a good choice to figure out an expression is true or false

2. examples

```
1 | select '437'
2 | -- just return return a cell that contains '437'
3 | -- quite useless
4 | -- may be use in ensure whether an expression is true
5 | select '437' as FOO
6 | -- generate a column name "FOO"
7 | -- do not alter any table
8 | select 'abcd' from {tab1}
9 | -- generate 1 column and n rows with 'abcd' in the cells
10 | -- even if tab1 hasn't such cells
```

Arithmetic Expression

1. **as** clause

modified the **display** name:

just show with the column name you want, **never alter the table itself**

```
1 | select {col} as {col_newname} from {tab}
```

2. **and, or**

1. functions like other programme language

2. precedence: and > or

3. we can use parentheses to enforce the precedence

```

1  -- these 2 statement are different
2  select * from {tab}
3  where ({cond1} or {cond2}) and ({cond3} or {cond4})
4
5  select * from {tab}
6  where {cond1} or {cond2} and {cond3} or {cond4}

```

3. comparison operators

1. basic comparison operators

```

1  <, <=, >, >=, =, !=, <>, =

```

2. !=, <>

Both means not equal to

Whether they are equivalent depends on the SQL. In postgresSQL, they are equivalent.

3. =

means **equals**

never use == as **equals** in postgresSQL

4. NULL judgement

```

1  -- never use {col1} = null as a filter
2  where {col1} is null;
3  where {col2} is not null

```

5. remark on **bigger** and **smaller**

means different for different **data types**

```

1  2 < 10 --true
2  '2' < '10' -- false, ASCII + lexicographical order
3  '2-JUN-1883' > '1-DEC-2056' -- compare as strings or dates? It differs
    in different products

```

4. in()

It can be used as the restriction for some columns are discrete range

a set is in the parentheses

```

1  where (country = 'us' or country = 'cn')
2  where country in('us', 'cn')

```

5. intervals

1. format:

```

1  where {col1} between {lowerbound} and {upperbound}

```

2. remark

`between {a} and {b}` indicates an interval `[a, b]`

3. example

```
1 -- query all 5-10 years old kids
2 where age between 5 and 10
3 -- query all kids whose name with a first character 'a' or 'b'
4 where name between 'A' and 'C' and name not like 'c%'
```

6. negation

1. claim: all comparison can be negated with `not`

2. examples

```
1 where country not in ('us', 'gb') or year not between 1940 and 1949;
2 -- by De Morgan's law, it's equivalent to
3 where not (country in ('us', 'gb') and year between 1940 and 1949);
```

7. match with **like**

1. With the usage of **like**, we can restrict a column of string to a specific pattern

2. wildcard

```
1 % -- meaning any number of characters, including none
2
3 _ -- one and only one character
```

3. skills

```
1 -- 1. we don't want any string in the {col} with a character 'A'
2 where {col} not like '%A%'
3
4 -- 2. we don't want any string in the {col} with 'a' or 'A'
5 where {col} not like '%A%' and not like '%a%'
6 where upper({col}) not like '%A%' -- Function called. Slow down the query
```

8. Date and Datetime

1. explicit cast is needed to avoid bad surprise when **comparing**

```
1 where post_date >= '2018-03-12'; -- bad habit
2 where post_date >= date('2018-03-12'); -- ok
```

2. More than one pattern of string can be converted to same date

```

1 'YYYY-MM-DD'
2 'YYYY/MM/DD'
3 'Mon DD, YYYY'
4 'Month DD, YYYY'
5 date('2018-3-12')
6 date('2018/3/12')
7 date('Mar 12, 2018')
8 date('March 12, 2018')

```

3. better way to convert a string to **date** or **timestamp**

0. Reference:

[PostgreSQL: Documentation: 12: 9.8. Data Type Formatting Functions](#)

1. syntax

| Function | Return Type | Description | Example |
|---------------------------------------|--------------------------|------------------------------|---|
| <code>to_date(text, text)</code> | date | convert string to date | <code>to_date('05 Dec 2000', 'DD Mon YYYY')</code> |
| <code>to_timestamp(text, text)</code> | timestamp with time zone | convert string to time stamp | <code>to_timestamp('05 Dec 2000', 'DD Mon YYYY')</code> |

2. Common format specifiers

date:

| Pattern | Description |
|---------|---|
| YYYY | year (4 or more digits) |
| Month | full capitalized month name (blank-padded to 9 chars) |
| Mon | abbreviated capitalized month name (3 chars in English, localized lengths vary) |
| MM | month number (01-12) |
| DD | day of month (01-31) |

timestamp:

| Pattern | Description |
|---------|---------------------|
| HH12 | hour of day (01-12) |
| HH24 | hour of day (00-23) |
| MI | minute (00-59) |

| Pattern | Description |
|---------|-----------------------|
| SS | second (00-59) |
| MS | millisecond (000-999) |

3. More syntax and format supported by postgresSQL

Reference:

[PostgreSQL: Documentation: 12: 9.8. Data Type Formatting Functions](#)

4. Comparing **date** and **timestamp**

A **date** will be automatically converted to **timestamp**, which has higher precision.

Its **time** will be automatically set to **'00:00:00'**

9. NULL

1. Boolean in sql can be **true**, **false**, **NULL**.

2. In SQL, logically, we say NULL means "we don't know whether true or false".

3. When a NULL is involved in a logical expression, we are hard to deduce the outcome.

4. there are some special cases:

```
1 | select true or NULL; -- true
2 | select false and NULL; -- false
```

5. to filter the **NULLs**, we should use `is NULL` or `is not NULL`;

Functions

1. show DDL of a table: in command line

```
1 | \d movies
```

2. Why using functions

One important feature of SQL is that you don't need to return data **exactly as it was stored**.

Operators, and many functions allow to return transformed data

Transforming displayed column in Select

It reduce the performance and sometimes harmful.

Never store something that can be computed from the original data at any time.

3. concatenating 2 strings

1. claims

`concat()` in MySQL, SQL server use `+`

In most products, including postgresSQL, use `||`

some other types , when becoming the operands of the `||` , will automatically be converted to the string

2. syntax:

```
1 | select [{col1} | {str1}] || [{col2} | {str2}] || [{col3} | {str3}]
2 | from {tab1}
```

3. example:

```
1 | select 'The code of ' || c.name || ' is ' || c.hex
2 | from color_names;
```

4. displayed colomns

| ?column? |
|-------------------------------------|
| The code of AliceBlue is #F0F8FF |
| The code of AntiqueWhite is #FAEBD7 |
| The code of Aqua is #00FFFF |
| The code of Aquamarine is #7FFFD4 |

4. as

1. claim

give a **alias** to a column and show in the console

2. example

```
1 | select 'The code of ' || c.name || ' is ' || c.hex as 'combine'
2 | from color_names;
```

| combine |
|-------------------------------------|
| The code of AliceBlue is #F0F8FF |
| The code of AntiqueWhite is #FAEBD7 |
| The code of Aqua is #00FFFF |
| The code of Aquamarine is #7FFFD4 |

5. type casting

```
1 | select cast({col1} as {type1}) from {tab1}
```

cast the displayed column to {type1}

6. case-end

1. aim: **maps** the **current column cells** to a **enumerate set** and generate a new column **in the console**

2. syntax1: for multi-columns condition

```
1 case when {cond1} then {result1}
2     when {cond2} then {result2}
3     .....
4     else {resultn}
5     end as {new_name}
6 from [table]
7 where {conditions}
8 -- the results will automatically form a column
```

```
1 -- example
2 -- two column will be shown in the console
3 select s.english_name,
4 case
5     when s.latitude is null then 'missing'
6     when s.district in ('Luohu', 'Futian', 'Nanshan') then 'Inside Area'
7     else 'Outside Area' end as area
8 from stations s;
```

syntax2: for single-column condition

```
1 case {col}
2     when {form1} then {result1}
3     when {form2} then {result2}
4     .....
5     else {resultn}
6     end as {new_name}
7 from [table]
8 where {conditions}
9 -- use '=' to match the col and form1, form2...
10 -- the results will automatically form a column
```

```
1 -- example
2 -- only one column will be shown in the console
3 select '=' ||
4 case s.district
5     when 'Luohu' then 1
6     when 'Futian' then 1
7     when 'Nanshan' then 1
8     else 0 end as Inside_or_not
9 from stations s
```

3. example: we can use it to extend the information

```

1 | select Name_
2 |     case gend
3 |         when 'F' then 'female'
4 |         when 'M' then 'male'
5 |         else 'unknown' -- we should deal with the NULL
6 |     end as 'gender'
7 | from people

```

7. String Functions

upper and lower

```

1 | -- convert a column or a string to uppercase or lowercase
2 | upper([col] | {str})
3 | lower([col] | {str})

```

trim

```

1 | -- delete some sybolic strings in the head or in the tail
2 | select trim([both | leading | trailing] {str_pattern} from [col],
3 | {str_text}) from {tab1};
4 |
5 | -- 'from {tab1}' can be omitted when no columns appear behind the SELECT
6 |
7 | --example
8 | select trim(trailing '.' from '10.00.....'); -- 10.00

```

substr

```

1 | -- from the begin_ position intercept string with a length of span_
2 | -- the first character in the string is 1, not 0
3 | substr([col] | {str_text}, {begin_}, {span_})
4 |
5 | --example
6 | select substr('hello world', 5, 3); -- 'o w'

```

replace

```

1 | -- replace all the str_pattern with new_pattern in the text
2 | replace([col] | {text}, {str_pattern}, {new_pattern})
3 |
4 | --example
5 | select replace('sheep', 'ee', 'i');

```

length

```

1 | -- compute the number of bytes of a string
2 | select length('hello'); -- 5
3 | select length('你好'); -- 2 in postgresSQL, depends on the product

```

8. Numerical functions

round and trunc

```
1  -- Round to retain specified significant figures
2  select round(50.123, 2); -- 50.12
3  select round(50.125, 2); -- 50.13
4
5  -- truncates a value to the specified precision
6  select trunc(123.456, 2); -- 123.45
7  select trunc(123.456, 0); -- 123
8  select trunc(123.456, -2); -- 100
```
